OCTOBER 28, 2021
BODY OF REPORT REDACTED TO ONLY INCLUDE THE INFORMATION NEEDED FOR THE SR400 BRIDGE DESIGN BUILD PROJECT.

Attention: Scott A. Gero, P.E. - Project Manager

Subject: SS Geotechnical Data Report
[redacted]
Project No [redacted] **PI No. 0001757**
Fulton and Forsyth Counties, Georgia
AECOM Project 60558412 – Task Order 5
NOVA Project Number 2018089

Dear Mr. Gero,

NOVA Engineering and Environmental, LLC (NOVA) has completed the Soil Survey (SS) Geotechnical Data Report (GDR) associated with the [redacted] project in Fulton [redacted] Counties, Georgia. This work has been performed under AECOM Task Order 5 of this project (Purchase Order Number 102551) and in general accordance with GDOT requirements as modified based on scoping meetings with HNTB and United Consulting.

An OMAT search for historical BFI reports and a Pavement Evaluation Study was previously completed under Task Order 3 of this project. A Bridge Foundation Investigation (BFI) GDR and [redacted] were performed under Task Order 5 and submitted under separate cover.

We thank you for the opportunity to assist you with this project and look forward to working with you on future projects.

Sincerely,
NOVA ENGINEERING AND ENVIRONMENTAL LLC

Yude Chen, P.E.
Project Engineer

Eric K. Tay, P.E.
Senior Engineer

J. Stephen Willenborg, P.E.
Project Manager

Randall L. Bagwell, P.E.
Project Principal

GEORGIA REGISTERED # 26477 PROFESSIONAL ENGINEER RANDALL L. BAGWELL

IMPORTANT INFORMATION ABOUT THIS GEOTECHNICAL-ENGINEERING REPORT

[redacted]

2. SOIL SURVEY INVESTIGATION

This SS GDR includes the results of geotechnical explorations performed in support of the design of roadway foundations and embankments on the project. The geotechnical explorations consisted of conducting Standard Penetration Test (SPT) borings for anticipated fill areas and auger borings in anticipated cut areas within the proposed SR 400 widening footprint, depending on accessibility. NB borings are those conducted for the northbound lanes and SB borings are those conducted for the southbound lanes. SPT borings were generally drilled to approximately 1 to 1.5 times the height of the anticipated new fill or a minimum of 5 feet unless shallow refusal was encountered. Auger only borings were generally drilled to approximately 5 feet deeper than the anticipated cut and/or ditch depths unless shallow refusal was encountered. The cut and fill depths were estimated based on available drawings provided and/or visual observations of the surrounding topography relative to existing roadway finished grades. The soil survey explorations were generally conducted along the SR 400 corridor[redacted]; additional details where test (SPT and Auger) borings were conducted are presented in Section 4 of this report.

3. GENERAL GEOLOGY

The site is located in the Piedmont Geologic Region, a broad northeasterly trending province underlain by crystalline rocks up to 600 million years old. The Piedmont Region is bounded by the Blue Ridge Range of the Appalachian Mountains to the northwest, and by the leading edge of Coastal Plain sediments, commonly referred to as the "Fall Line" to the southeast. Numerous episodes of crystal deformation have produced varying degrees of metamorphism, folding and shearing in the underlying rock. The resulting metamorphic rock types in the project area are predominantly a series of Precambrian-Paleozoic age.

Residual soils in the region are primarily derived from the in-situ parent rock by chemical weathering. The extent of the weathering is influenced by the mineral composition of the rock and defects such as fissures, faults and fractures. The residual profile can generally be divided into three zones:

- An upper zone near the ground surface consisting of red clays and clayey silts which have undergone the most advanced weathering,
- An intermediate zone of less weathered micaceous sandy silts and silty sands, frequently described as "saprolite", whose mineralogy, texture and banded appearance reflects the structure of the original rock, and
- A transitional zone between soil and rock termed partially weathered rock (PWR).

The boundaries between zones of soil, partially weathered rock, and bedrock are erratic and poorly defined. Weathering is often more advanced next to fractures and joints that transmit water, and in mineral bands. Boulders and rock lenses are sometimes encountered within PWR or soil matrix. Consequently, significant fluctuations in depths to materials may occur over short horizontal distances.

The General Project Geology Map is shown as Figure 2 of Appendix A.

4. FIELD EXPLORATION

The number of borings, their locations, and the proposed depth for each boring were determined by reviewing available subsurface exploration data, proposed locations of the new planned bridges/walls and the new roadway plans, profiles, and cross-sections to define the proposed cut and fill heights, in general accordance with GDOT requirements as modified based on scoping meetings with HNTB and United Consulting. Test boring locations were based on proposed SR 400 roadway widening layouts provided by AECOM at the time of the field exploration. Boring locations were placed at regular intervals within the proposed SR 400 widening footprint at select locations. Test boring locations were established in the field by NOVA personnel using a handheld GPS device, and measuring distances from permanent site landmarks. Therefore, the locations noted should be considered approximate. Some boring locations were offset to drill "rig-accessible" areas based on site grades, or located at safe distances from marked utility lines at the time of drilling. Please refer to Figures 3-1 through 3-40 of Appendix A for the approximate boring locations drilled. The proposed SR 400 construction centerline is included on these figures. Please note that proposed roadway alignment layout, configurations, or other information may have changed after the field exploration was completed.

Utilities at the proposed boring locations were located by calling Georgia 811 prior to completing the test borings. GDOT Intelligent Transportation System (ITS) buried fiber optics cables were not located by Georgia 811. NOVA coordinated with the GDOT ITS Department and were provided pdf drawings of the Advanced Traffic Management System (ATMS) Plans for the project corridor. NOVA's field engineers met with GDOT ITS Supervisor and personnel from the GDOT Traffic Management Center (TMC) on site at several locations to review fiber optic line plans. Some of the boring locations required Private Utility Locator services to locate utilities. Hand clearing/dozer clearing was required to access some of the boring locations.

Our drilling subcontractor, TTL, performed all test borings under the supervision of Accura Engineering's field engineer. Borings were drilled with All-Terrain Vehicles (ATV) or truck mounted drill-rigs equipped with hollow-stem continuous flight augers. The SPT N-values were obtained using automatic hammers. Calibration information for the SPT hammers utilized on this project are included as Attachments to this report. The SPTs were conducted using a standard 1.4-inch I.D., 2.0-inch O.D., split-tube sampler per ASTM D1586 and were performed at depth intervals in general accordance with GDOT OMAT guidelines. Representative portions

of the soil samples, obtained from the sampler, were placed in air-tight glass jars and transported to our laboratory for further evaluation and testing.

Auger refusal occurs when very hard or very dense material, frequently boulders or the upper surface of bedrock, is encountered and cannot be penetrated by a power auger. In some cases, when auger refusal was encountered at shallow depths that were not supported by the surficial features, offset borings were performed to confirm auger refusal and/or the presence of partially weathered rock (PWR) at deeper depths. Partially weathered rock (PWR) is a transitional material between soil and the underlying parent rock that is defined as residual materials that exhibit a standard penetration resistance (SPT N-value) exceeding 100 bpf.

It should be noted that the SPT N-value in fill materials may be amplified or result in auger refusal by the presence of graded aggregate base, rock fragments, treated or cemented subgrade materials, or other very hard materials.

The groundwater levels reported on the Test Boring Records represent measurements made at the completion of the test borings or the next day after boring completion, where noted. The soil test borings were backfilled immediately upon completion with soil cuttings and patched with asphalt/concrete as needed.

Coordinates and elevations of the boring locations were surveyed and provided by ACCURA Engineering after the borings were completed. The coordinates and elevations at the borings are based on North American Datum of 1983 (NAD 83 CORS94) and North American Vertical Datum of 1988 (NAVD 88), respectively.

5. SOIL CLASSIFICATION AND LABORATORY TESTING

Soil Classification: Soil classification provides a general guide to the engineering properties of various soil types and enables the engineer to apply past experience to current problems. Samples obtained during drilling operations were classified by an engineer using visual-manual procedures in general accordance with ASTM D2488. The soils were classified according to relative density/consistency (based on SPT N-values), color and composition. Visual classification is confirmed/corrected based on the laboratory test results from representative soil samples obtained from each major soil layer. The final soil classification descriptions included on the "Test Boring Records" are based on using the Unified Soil Classification System in general accordance with ASTM D2487.

Laboratory Testing: The following laboratory testing were performed on representative soil samples collected during the field exploration to assist in the soil classification, and to provide pavement support and soil corrosivity data:

- Grain Size Analysis – ASTM D6913
- Moisture Content – ASTM D2216

- Atterberg Limits – ASTM D4318
- Materials Class Testing – GDT 810.2
- California Bearing Ratio – ASTM D1883
- Soil Resistivity – AASHTO T 288
- pH of Soils – ASTM D 4972

Grain Size Analysis: The grain size analysis consists of determining the amounts of various sizes of soil particles using a series of standard sieve openings. The percentage of soil, by weight, passing the individual sieves is then recorded and typically presented in a graphical and/or tabular format. The percentage of fines passing through the No. 200 sieve is generally considered to represent the amount of silt and clay of the tested soil sample. The sieve analysis tests were conducted in general accordance with ASTM D6913 - Standard Test Methods for Particle Size Distribution Using Sieve Analysis.

Moisture Content: In a given soil-air-water matrix, the moisture content is the ratio expressed as a percentage of the weight of water to the weight of the soil particles. These tests were conducted in general accordance with ASTM D2216 - Standard Test Methods for Laboratory Determination of Water (Moisture) Content of Soil and Rock by Mass.

Atterberg Limits: The Atterberg Limits are different descriptions of the moisture content of fine-grained soils as it transitions between a solid to a liquid-state. For classification purposes the two primary Atterberg Limits used are the Plastic Limit (PL) and the Liquid Limit (LL). The Plasticity Index (PI) is also calculated for soil classification, which is defined as the difference between Liquid Limit and Plastic Limit. The Plastic Limit (PL) is the moisture content at which a soil transitions from a semisolid state to a plastic state. The Liquid Limit (LL) is defined as the moisture content at which a soil transitions from a plastic state to a liquid state. Atterberg Limits tests were performed in general accordance with ASTM D4318 - Standard Test Methods for Liquid Limit, Plastic Limit, and Plasticity Index of Soils.

California Bearing Ratio: The California Bearing Ratio (CBR) is used to determine the strength of subgrade, subbase, or base course materials, including recycled materials for use in the design of road pavements. The test method is primarily intended for, but not limited to, evaluating the strength of materials having maximum particle sizes less than ¾-in. The CBR value obtained in this test can be used to determine the soil support value (SSV) to be used in pavement design. CBR tests were performed in general accordance with ASTM D1883 - Standard Test Method for California Bearing Ratio (CBR) of Laboratory-Compacted Soils.

Materials Class Testing: The GDOT materials class is used for roadway construction per GDOT Section 810.2 requirements of the GDOT Standard Specifications Construction of Transportation Systems. These tests were typically conducted on bulk soil samples from auger only borings in potential cut areas. The GDT 810.2 testing consists of three (3) tests to determine soil gradation (GDT 4 Method), volume change (GDT 6 Method), and maximum density (GDT 7 or GDT 67 Method). The material classes are generally divided into six (6)

major classes: Class I through Class VI. Class I through Class III are further subdivided by description and physical property per GDOT specifications

Soil Resistivity: Soil resistivity is used to determine the corrosivity of soil and identify the conditions under which the corrosion of metals or concrete in soil may be accentuated. Resistivity is a measure of the resistance to flow of electrical current through the soil. Resistivity, the inverse of conductivity, is measured in units of ohm-centimeters. The soil resistivity tests were performed in general accordance with AASHTO T 288 - Standard Method of Test for Determining Minimum Laboratory Soil Resistivity

pH: pH is an expression of the concentration of dissociated hydrogen ions present in an aqueous solution. pH values range from 1 to 14, with values below 7 indicating acidic conditions and values above 7 indicating alkaline conditions. This test is performed using a calibrated electronic pH meter with a sensing probe. The meter is calibrated by immersing the probe in a solution with a known pH. These tests were performed in general accordance with ASTM D 4972 - Standard Test Method for pH of Soils.

6. GEOTECHNICAL EXPLORATION DATA

6.1 SUBSURFACE DATA

The results of the soil survey study are presented and attached to this report. [redacted]

Tables 1 and 2 provide a summary of the soil survey boring locations and field exploration quantities for the widening of the northbound and southbound roadways, respectively. The approximate boring locations are shown on Figures 3-1 through 3-40 of Appendix A. The results of the field exploration, USCS soil classifications, and laboratory tests results are presented in Test Boring Records in Appendix B. The Test Boring Records include Atterberg limits (Plastic Limit and Liquid Limit) and moisture content within the “Graphic Depiction” of the log.

7. LIMITATIONS

This report includes the summary of the data collection effort per the authorized scope of the work and is based on generally accepted geotechnical engineering practices. The stratification lines and depth designations on the Test Boring Records represent approximate boundaries between various subsurface strata. Actual transitions between soil strata may be gradual. No warranties/guarantees are expressed or implied.

This report is intended for the sole use of AECOM, HNTB and the Georgia Department of Transportation. The scope of work performed during this study was developed for purposes specifically intended by AECOM, HNTB and the Georgia Department of Transportation and may not satisfy other users' requirements. Use of this report or the data included herein will be at the sole risk of any third-party user. NOVA is not responsible or liable for the interpretation by others of the data in this report, nor their conclusions, recommendations or opinions.

Fill soils on site may not have documentation relating to their type, placement and compaction effort. Therefore, variability of soils and compaction efforts in the existing fill soils encountered in the borings should be expected. Selection of engineering properties based on SPT N-values in the fill soils should consider the variability in soil type, placement, and compaction effort. Our scope of work was limited to the exploration as detailed herein. When atypical conditions in the fill soils such as high N-values are reported, additional assessment and/or exploration of these conditions may be necessary prior to including these atypical aspects in the design.

Our professional services have been performed, our findings obtained and presented in accordance with generally accepted geotechnical engineering principles and practices in the State of Georgia. This report is intended to be a geotechnical data report with no engineering conclusions or recommendations provided. Please see the attached "Important Information about This Geotechnical Engineering Report" for details.

Northbound Boring logs

KEY TO SYMBOLS AND CLASSIFICATIONS

Drilling Symbols

	Split Spoon Sample
	Bulk Sample
	SPT Sample
	Undisturbed Sample (UD)
	Standard Penetration Resistance (ASTM D1586)
	Water Table at least 24 Hours after Drilling
	Water Table 1 Hour or less after Drilling
100/2”	Number of Blows (100) to Drive the Spoon a Number of Inches (2)
NX, NQ	Core Barrel Sizes: 2⅛- and 2-Inch Diameter Rock Core, Respectively
REC	Percentage of Rock Core Recovered
RQD	Rock Quality Designation – Percentage of Recovered Core Segments 4 or more Inches Long
	Loss of Drilling Water
MC	Moisture Content Test Performed
N/E	Not Encountered
N/M	Not Measured
	Caving

Strata Symbols

	Paving
	Gravel /Graded Aggregate Base
	Fill
	Clayey Sand
	Silty Sand
	Sandy Silt/Silt
	Low Plasticity Clay
	Partially Weathered Rock
	High Plasticity Clay
	Topsoil
	Alluvium
	Poorly Graded Sand with Silt

NOVA

CORRELATION OF PENETRATION RESISTANCE WITH RELATIVE DENSITY AND CONSISTENCY

	Number of Blows, "N"	Approximate Relative Density
	0 – 4	Very Loose
	5 – 10	Loose
SANDS	11 – 30	Medium Dense
	31 – 50	Dense
	Over 50	Very Dense

	Number of Blows, "N"	Approximate Consistency
	0 – 2	Very Soft
	3 – 4	Soft
SILTS	5 – 8	Firm
and	9 – 15	Stiff
CLAYS	16 – 30	Very Stiff
	31 – 50	Hard
	Over 50	Very Hard

DRILLING PROCEDURES

Soil sampling and standard penetration testing performed in accordance with ASTM D1586. The standard penetration resistance is the number of blows of a 140 pound hammer falling 30 inches to drive a 2-inch O.D., 1⅜-inch I.D. split spoon sampler one foot. The undisturbed sampling procedure is described by ASTM D1587.

SOIL CLASSIFICATION CHART

COARSE GRAINED SOILS	**GRAVELS**	Clean Gravel less than 5% fines	GW	Well graded gravel
			GP	Poorly graded gravel
		Gravels with Fines more than 12% fines	GM	Silty gravel
			GC	Clayey gravel
	SANDS	Clean Sand less than 5% fines	SW	Well graded sand
			SP	Poorly graded sand
		Sands with Fines more than 12% fines	SM	Silty sand
			SC	Clayey sand
FINE GRAINED SOILS	**SILTS AND CLAYS** Liquid Limit less than 50	Inorganic	CL	Lean clay
			ML	Silt
		Organic	OL	Organic clay and silt
	SILTS AND CLAYS Liquid Limit 50 or more	Inorganic	CH	Fat clay
			MH	Elastic silt
		Organic	OH	Organic clay and silt
HIGHLY ORGANIC SOILS		Organic matter, dark color, organic odor	PT	Peat

PARTICLE SIZE IDENTIFICATION

GRAVELS	Coarse	¾ inch to 3 inches
	Fine	No. 4 to ¾ inch
SANDS	Coarse	No. 10 to No. 4
	Medium	No. 40 to No. 10
	Fine	No. 200 to No. 40
SILTS AND CLAYS		Passing No. 200

									[d]Average Measured Energy:		311.0	88.8%	

Overall Average ETR %

[a]Energy results for SPT sampling are averaged and reported for hammer impacts during the final 1 ft of driving, which relates to the observed N-value. In some cases, certain blows produce poor quality data and were not used to calculate the Average Measured Energy. This may result in less blows evalutated for ETR than what is shown on the boring logs.

[b]Measured Energy is based on the EFV method, as outlined in ASTM D4633-10, for each blow recorded by the SPT Analyzer.

[c]Energy Transfer Ratio is the Measured Energy divided by the theoretical SPT energy of 350 foot-pounds (140 pound hammer falling 2.5 feet).

The average EFV and ETR values may differ slightly and insignificantly from those in the PDIPLOT tables due to roundoff.

[d]The overall Average Measured Energy is calculated by taking the weighted average of the number of hammer blows analyzed (last 1 ft) and the Average Measured Energy for each sample depth tested.

[e]ETR COV determined by calculating the overall standard deviation for the average ETR per sample depth (c) and then dividing by the overall average ETR.

The STDEV function from Excel was utilized to determine the standard deviation.

						50.8	18.63	13.5 - 15.0	12 - 14 - 9	23	293.5	83.9%	2
									[d]Average Measured Energy:		292.4	83.5%	

Overall Average ETR %

[a]Energy results for SPT sampling are averaged and reported for hammer impacts during the final 1 ft of driving, which relates to the observed N-value. In some cases, certain blows produce poor quality data and were not used to calculate the Average Measured Energy. This may result in less blows evalutated for ETR than what is shown on the boring logs.

[b]Measured Energy is based on the EFV method, as outlined in ASTM D4633-10, for each blow recorded by the SPT Analyzer.

[c]Energy Transfer Ratio is the Measured Energy divided by the theoretical SPT energy of 350 foot-pounds (140 pound hammer falling 2.5 feet).

The average EFV and ETR values may differ slightly and insignificantly from those in the PDIPLOT tables due to roundoff.

[d]The overall Average Measured Energy is calculated by taking the weighted average of the number of hammer blows analyzed (last 1 ft) and the Average Measured Energy for each sample depth tested.

[e]ETR COV determined by calculating the overall standard deviation for the average ETR per sample depth (c) and then dividing by the overall average ETR.

The STDEV function from Excel was utilized to determine the standard deviation.

									[d]Average Measured Energy:		322.2	92.1%	

Overall Average ETR %

[a]Energy results for SPT sampling are averaged and reported for hammer impacts during the final 1 ft of driving, which relates to the observed N-value. In some cases, certain blows produce poor quality data and were not used to calculate the Average Measured Energy. This may result in less blows evalutated for ETR than what is shown on the boring logs.

[b]Measured Energy is based on the EFV method, as outlined in ASTM D4633-10, for each blow recorded by the SPT Analyzer.

[c]Energy Transfer Ratio is the Measured Energy divided by the theoretical SPT energy of 350 foot-pounds (140 pound hammer falling 2.5 feet).

The average EFV and ETR values may differ slightly and insignificantly from those in the PDIPLOT tables due to roundoff.

[d]The overall Average Measured Energy is calculated by taking the weighted average of the number of hammer blows analyzed (last 1 ft) and the Average Measured Energy for each sample depth tested.

[e]ETR COV determined by calculating the overall standard deviation for the average ETR per sample depth (c) and then dividing by the overall average ETR.

The STDEV function from Excel was utilized to determine the standard deviation.

Statistical Analysis - Overall Coefficient of Variation

IMPORTANT INFORMATION ABOUT THIS GEOTECHNICAL ENGINEERING REPORT

Important Information about This

Geotechnical-Engineering Report

Subsurface problems are a principal cause of construction delays, cost overruns, claims, and disputes.

While you cannot eliminate all such risks, you can manage them. The following information is provided to help.

The Geoprofessional Business Association (GBA) has prepared this advisory to help you – assumedly a client representative – interpret and apply this geotechnical-engineering report as effectively as possible. In that way, clients can benefit from a lowered exposure to the subsurface problems that, for decades, have been a principal cause of construction delays, cost overruns, claims, and disputes. If you have questions or want more information about any of the issues discussed below, contact your GBA-member geotechnical engineer. Active involvement in the Geoprofessional Business Association exposes geotechnical engineers to a wide array of risk-confrontation techniques that can be of genuine benefit for everyone involved with a construction project.

Geotechnical-Engineering Services Are Performed for Specific Purposes, Persons, and Projects

Geotechnical engineers structure their services to meet the specific needs of their clients. A geotechnical-engineering study conducted for a given civil engineer will not likely meet the needs of a civil-works constructor or even a different civil engineer. Because each geotechnical-engineering study is unique, each geotechnical-engineering report is unique, prepared *solely* for the client. *Those who rely on a geotechnical-engineering report prepared for a different client can be seriously misled*. No one except authorized client representatives should rely on this geotechnical-engineering report without first conferring with the geotechnical engineer who prepared it. *And no one – not even you – should apply this report for any purpose or project except the one originally contemplated.*

Read this Report in Full

Costly problems have occurred because those relying on a geotechnical-engineering report did not read it *in its entirety*. Do not rely on an executive summary. Do not read selected elements only. *Read this report in full.*

You Need to Inform Your Geotechnical Engineer about Change

Your geotechnical engineer considered unique, project-specific factors when designing the study behind this report and developing the confirmation-dependent recommendations the report conveys. A few typical factors include:

- the client's goals, objectives, budget, schedule, and risk-management preferences;
- the general nature of the structure involved, its size, configuration, and performance criteria;
- the structure's location and orientation on the site; and
- other planned or existing site improvements, such as retaining walls, access roads, parking lots, and underground utilities.

Typical changes that could erode the reliability of this report include those that affect:

- the site's size or shape;
- the function of the proposed structure, as when it's changed from a parking garage to an office building, or from a light-industrial plant to a refrigerated warehouse;
- the elevation, configuration, location, orientation, or weight of the proposed structure;
- the composition of the design team; or
- project ownership.

As a general rule, *always* inform your geotechnical engineer of project changes – even minor ones – and request an assessment of their impact. *The geotechnical engineer who prepared this report cannot accept responsibility or liability for problems that arise because the geotechnical engineer was not informed about developments the engineer otherwise would have considered.*

This Report May Not Be Reliable

Do not rely on this report if your geotechnical engineer prepared it:

- for a different client;
- for a different project;
- for a different site (that may or may not include all or a portion of the original site); or
- before important events occurred at the site or adjacent to it; e.g., man-made events like construction or environmental remediation, or natural events like floods, droughts, earthquakes, or groundwater fluctuations.

Note, too, that it could be unwise to rely on a geotechnical-engineering report whose reliability may have been affected by the passage of time, because of factors like changed subsurface conditions; new or modified codes, standards, or regulations; or new techniques or tools. *If your geotechnical engineer has not indicated an "apply-by" date on the report, ask what it should be*, and, in general, *if you are the least bit uncertain* about the continued reliability of this report, contact your geotechnical engineer before applying it. A minor amount of additional testing or analysis – if any is required at all – could prevent major problems.

Most of the "Findings" Related in This Report Are Professional Opinions

Before construction begins, geotechnical engineers explore a site's subsurface through various sampling and testing procedures. *Geotechnical engineers can observe actual subsurface conditions only at those specific locations where sampling and testing were performed*. The data derived from that sampling and testing were reviewed by your geotechnical engineer, who then applied professional judgment to form opinions about subsurface conditions throughout the site. Actual sitewide-subsurface conditions may differ – maybe significantly – from those indicated in this report. Confront that risk by retaining your geotechnical engineer to serve on the design team from project start to project finish, so the individual can provide informed guidance quickly, whenever needed.

This Report's Recommendations Are Confirmation-Dependent

The recommendations included in this report – including any options or alternatives – are confirmation-dependent. In other words, *they are not final*, because the geotechnical engineer who developed them relied heavily on judgment and opinion to do so. Your geotechnical engineer can finalize the recommendations *only after observing actual subsurface conditions* revealed during construction. If through observation your geotechnical engineer confirms that the conditions assumed to exist actually do exist, the recommendations can be relied upon, assuming no other changes have occurred. *The geotechnical engineer who prepared this report cannot assume responsibility or liability for confirmation-dependent recommendations if you fail to retain that engineer to perform construction observation.*

This Report Could Be Misinterpreted

Other design professionals' misinterpretation of geotechnical-engineering reports has resulted in costly problems. Confront that risk by having your geotechnical engineer serve as a full-time member of the design team, to:

- confer with other design-team members,
- help develop specifications,
- review pertinent elements of other design professionals' plans and specifications, and
- be on hand quickly whenever geotechnical-engineering guidance is needed.

You should also confront the risk of constructors misinterpreting this report. Do so by retaining your geotechnical engineer to participate in prebid and preconstruction conferences and to perform construction observation.

Give Constructors a Complete Report and Guidance

Some owners and design professionals mistakenly believe they can shift unanticipated-subsurface-conditions liability to constructors by limiting the information they provide for bid preparation. To help prevent the costly, contentious problems this practice has caused, include the complete geotechnical-engineering report, along with any attachments or appendices, with your contract documents, *but be certain to note conspicuously that you've included the material for informational purposes only*. To avoid misunderstanding, you may also want to note that "informational purposes" means constructors have no right to rely on the interpretations, opinions, conclusions, or recommendations in the report, but they may rely on the factual data relative to the specific times, locations, and depths/elevations referenced. Be certain that constructors know they may learn about specific project requirements, including options selected from the report, *only* from the design drawings and specifications. Remind constructors that they may perform their own studies if they want to, and *be sure to allow enough time* to permit them to do so. Only then might you be in a position to give constructors the information available to you, while requiring them to at least share some of the financial responsibilities stemming from unanticipated conditions. Conducting prebid and preconstruction conferences can also be valuable in this respect.

Read Responsibility Provisions Closely

Some client representatives, design professionals, and constructors do not realize that geotechnical engineering is far less exact than other engineering disciplines. That lack of understanding has nurtured unrealistic expectations that have resulted in disappointments, delays, cost overruns, claims, and disputes. To confront that risk, geotechnical engineers commonly include explanatory provisions in their reports. Sometimes labeled "limitations," many of these provisions indicate where geotechnical engineers' responsibilities begin and end, to help others recognize their own responsibilities and risks. *Read these provisions closely*. Ask questions. Your geotechnical engineer should respond fully and frankly.

Geoenvironmental Concerns Are Not Covered

The personnel, equipment, and techniques used to perform an environmental study – e.g., a "phase-one" or "phase-two" environmental site assessment – differ significantly from those used to perform a geotechnical-engineering study. For that reason, a geotechnical-engineering report does not usually relate any environmental findings, conclusions, or recommendations; e.g., about the likelihood of encountering underground storage tanks or regulated contaminants. *Unanticipated subsurface environmental problems have led to project failures*. If you have not yet obtained your own environmental information, ask your geotechnical consultant for risk-management guidance. As a general rule, *do not rely on an environmental report prepared for a different client, site, or project, or that is more than six months old.*

Obtain Professional Assistance to Deal with Moisture Infiltration and Mold

While your geotechnical engineer may have addressed groundwater, water infiltration, or similar issues in this report, none of the engineer's services were designed, conducted, or intended to prevent uncontrolled migration of moisture – including water vapor – from the soil through building slabs and walls and into the building interior, where it can cause mold growth and material-performance deficiencies. Accordingly, ***proper implementation of the geotechnical engineer's recommendations will not of itself be sufficient to prevent moisture infiltration.*** Confront the risk of moisture infiltration by including building-envelope or mold specialists on the design team. ***Geotechnical engineers are not building-envelope or mold specialists.***
